

Pointers and dynamic objects

Topics

- **Pointers**
 - Memory addresses
 - Declaration
 - Dereferencing a pointer
 - Pointers to pointer
- **Static vs. dynamic objects**
 - `new` and `delete`

Computer Memory

- Each variable is assigned a memory slot (the size depends on the data type) and the variable's data is stored there

Pointers

- A pointer is a variable used to store the address of a memory cell.
- We can use the pointer to reference this memory cell

Pointer Types

- Pointer
 - C++ has pointer types for each type of object
 - Pointers to `int` objects
 - Pointers to `char` objects
 - Pointers to user-defined objects
(e.g., `RationalNumber`)
 - Even pointers to pointers
 - Pointers to pointers to `int` objects

Pointer Variable

- Declaration of Pointer variables

```
type* pointer_name;  
//or  
type *pointer_name;
```

where *type* is the type of data pointed to (e.g. int, char, double)

Examples:

```
int *n;  
RationalNumber *r;  
int **p;    // pointer to pointer
```

Address Operator &

- *The "address of" operator (&)* gives the memory address of the variable
 - Usage: `&variable_name`

Memory address: 1020 1024

a

```
int a = 100;
//get the value,
cout << a;    //prints 100
//get the memory address
cout << &a;   //prints 1024
```

Address Operator &

```
#include <iostream>
using namespace std;
void main() {
    int a, b;
    a = 88;
    b = 100;

    cout << "The address of a is: " << &a << endl;
    cout << "The address of b is: " << &b << endl;
}
```

- Result is:
The address of a is: 1020
The address of b is: 1024

Pointer Variables

```
int a = 100;  
int *p = &a;  
cout << a << " " << &a <<endl;  
cout << p << " " << &p <<endl;
```

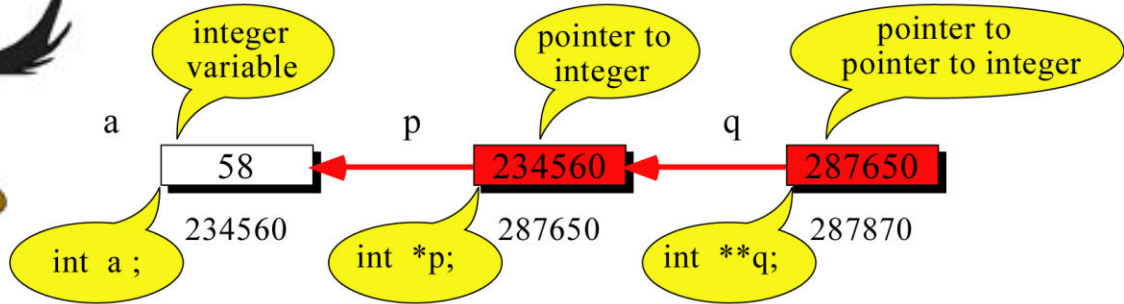

● Result is:
100 1024
1024 1032

- The value of pointer `p` is the address of variable `a`
- A pointer is also a variable, so it has its own memory address

Pointer to Pointer

```
// Local Declarations
int    a ;
int    *p ;
int    **q ;
```

```
// Statements
a = 58 ;
p = &a ;
q = &p ;
cout <<    a << " ";
cout <<    *p << " ";
cout <<    **q << " ";
```

What is the output?

58 58 58

Dereferencing Operator *

- We can access to the value stored in the variable pointed to by using the dereferencing operator (*),

```
int a = 100;
int *p = &a;
cout << a << endl;
cout << &a << endl;
cout << p << " " << *p << endl;
cout << &p << endl;
```

● Result is:

```
100
1024
1024 100
1032
```

Don't get confused

- Declaring a pointer means only that it is a pointer: `int *p;`
- Don't be confused with the dereferencing operator, which is also written with an asterisk (*). They are simply two different tasks represented with the same sign

```
int a = 100, b = 88, c = 8;
int *p1 = &a, *p2, *p3 = &c;
p2 = &b;    // p2 points to b
p2 = p1;    // p2 points to a
b = *p3;    // assign c to b
*p2 = *p3;  // assign c to a
cout << a << b << c;
```

● **Result is:**
888

A Pointer Example

The code

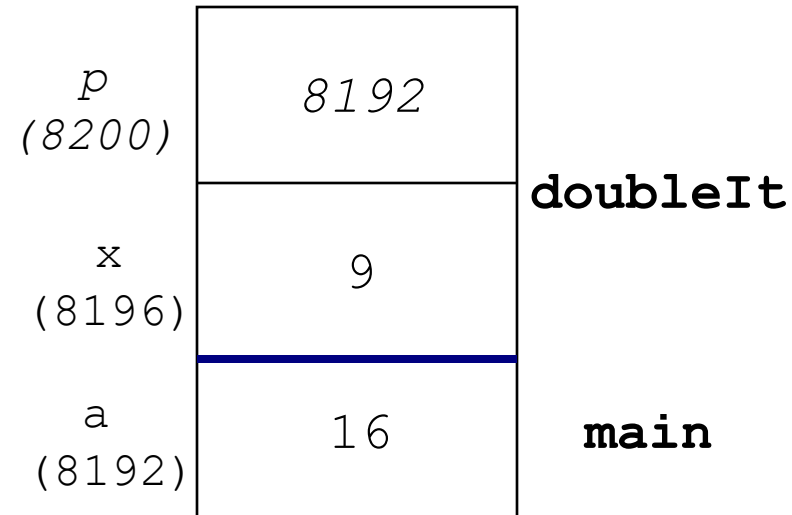

```
void doubleIt(int x,  
             int * p)  
{  
    *p = 2 * x;  
}  
  
int main(int argc, const  
        char * argv[])  
{  
    int a = 16;  
    doubleIt(9, &a);  
    return 0;  
}
```

a gets 18

Box diagram

Memory Layout

Another Pointer Example

```
#include <iostream>
using namespace std;
int main (){
    int value1 = 5, value2 = 15;
    int *p1, *p2;
    p1 = &value1; // p1 = address of value1
    p2 = &value2; // p2 = address of value2
    *p1 = 10;     // value pointed to by p1=10
    *p2 = *p1;    // value pointed to by p2= value
                 // pointed to by p1
    p1 = p2;     // p1 = p2 (pointer value copied)
    *p1 = 20;    // value pointed to by p1 = 20
    cout << "value1==" << value1 << "/ value2==" <<
    value2;
    return 0;
}
```

- **Let's figure out:
value1==? / value2==?
Also, p1=? p2=?**

Another Pointer Example

```
int a = 3;  
char s = 'z';  
double d = 1.03;  
int *pa = &a;  
char *ps = &s;  
double *pd = &d;
```

`% sizeof returns the # of bytes...`

```
cout << sizeof(pa) << sizeof(*pa)  
      << sizeof(&pa) << endl;  
cout << sizeof(ps) << sizeof(*ps)  
      << sizeof(&ps) << endl;  
cout << sizeof(pd) << sizeof(*pd)  
      << sizeof(&pd) << endl;
```

Reference Variables

A reference is an additional name to an existing memory location

Pointer:

```
int x=9;  
int *ref;  
ref = &x;
```

Reference:

```
int x = 9;  
int &ref = x;
```

Reference Variables

- A **reference variable** serves as an alternative name for an object

```
int m = 10;
int &j = m; // j is a reference variable
cout << "value of m = " << m << endl;
           //print 10

j = 18;
cout << "value of m = " << m << endl;
           // print 18
```

Reference Variables

- A **reference variable** always refers to the same object. Assigning a reference variable with a new value actually changes the value of the referred object.
- **Reference** variables are commonly used for parameter passing to a function

Traditional Pointer Usage

```
void IndirectSwap(char *Ptr1, char *Ptr2) {  
    char temp = *Ptr1;  
    *Ptr1 = *Ptr2;  
    *Ptr2 = temp;  
}  
  
int main() {  
    char a = 'y';  
    char b = 'n';  
    IndirectSwap(&a, &b);  
    cout << a << b << endl;  
    return 0;  
}
```

Pass by Reference

```
void IndirectSwap(char& y, char& z) {  
    char temp = y;  
    y = z;  
    z = temp;  
}  
  
int main() {  
    char a = 'y';  
    char b = 'n';  
    IndirectSwap(a, b);  
    cout << a << b << endl;  
    return 0;  
}
```

Pointers and Arrays

- ✉ The name of an array points only to the first element not the whole array.

The name of an array is a pointer constant to its first element

Array Name is a pointer constant

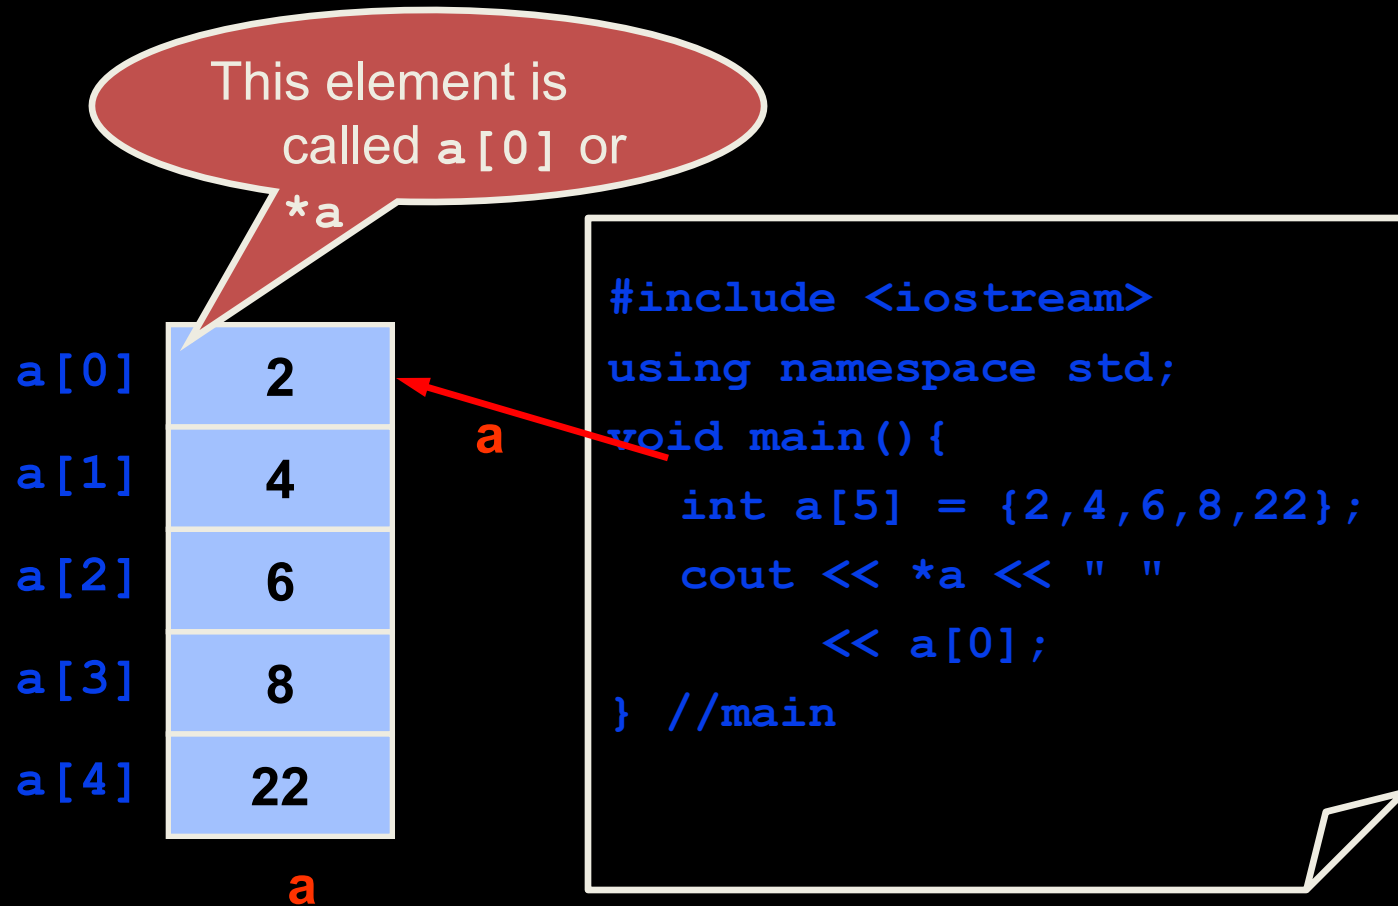

```
#include <iostream>
using namespace std;

void main () {
    int a[5];
    cout << "Address of a[0]: " << &a[0] << endl
         << "Name as pointer: " << a << endl;
}
```

Result:

```
Address of a[0]: 0x0065FDE4
Name as pointer: 0x0065FDE4
```

Dereferencing An Array Name

Array Names as Pointers

- ✉ To access an array, any pointer to the first element can be used instead of the name of the array.

We could replace `*p` by `*a`

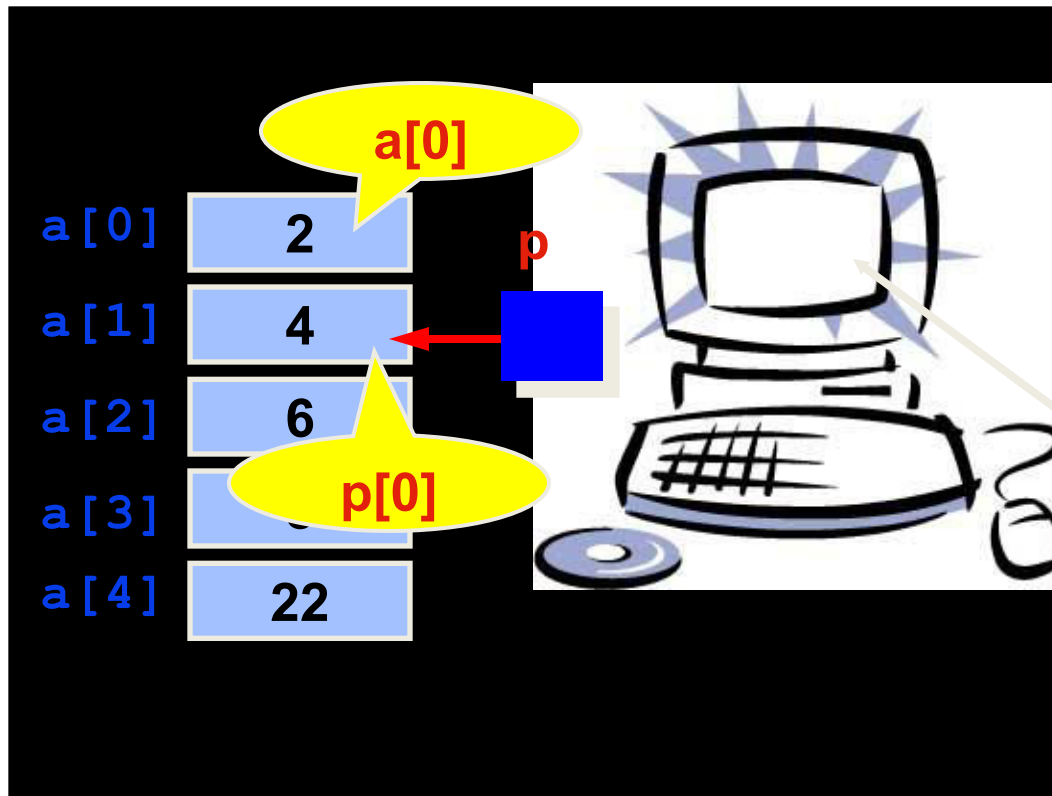

```
#include <iostream>
using namespace std;
void main() {
    int a[5] = {2,4,6,8,22};
    int *p = a;
    cout << a[0] << " "
         << *p;
}
```

Multiple Array Pointers

✉ Both `a` and `p` are pointers to the same array.

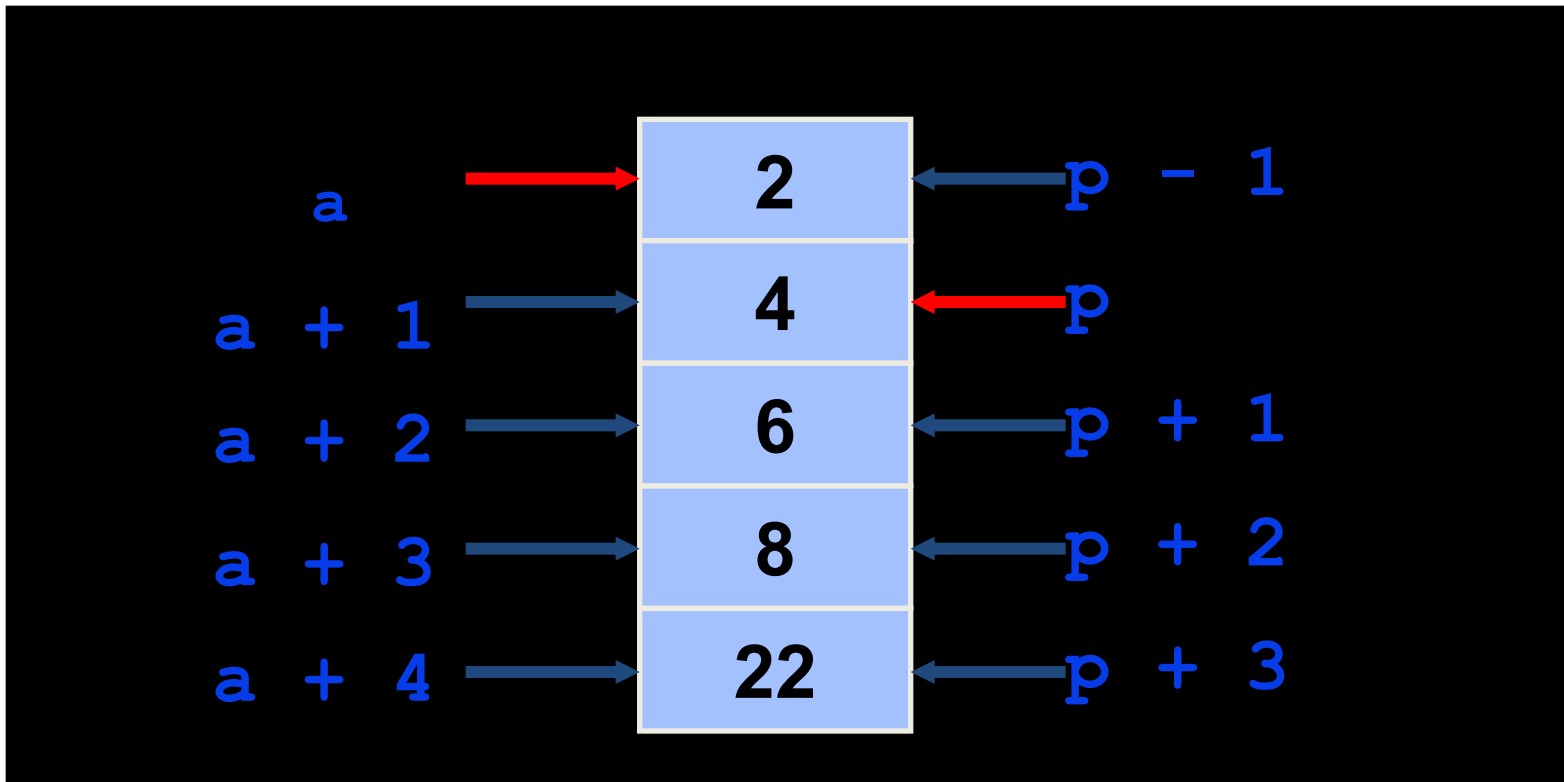

The diagram illustrates an array `a` with five elements: `a[0]` (2), `a[1]` (4), `a[2]` (6), `a[3]` (unknown), and `a[4]` (22). A pointer `p` is shown pointing to the element at `a[1]`. A yellow callout bubble labeled `a[0]` points to the value 2, and another yellow callout bubble labeled `p[0]` points to the value 4. A computer icon is also present, with a white arrow pointing from the code block to its monitor.

```
#include <iostream>
using namespace std;
void main(){
    int a[5] = {2,4,6,8,22};
    int *p = &a[1];
    cout << a[0] << " "
         << p[-1];
    cout << a[1] << " "
         << p[0];
}
```

Pointer Arithmetic

- ✉ Given a pointer p , $p+n$ refers to the element that is offset from p by n positions.

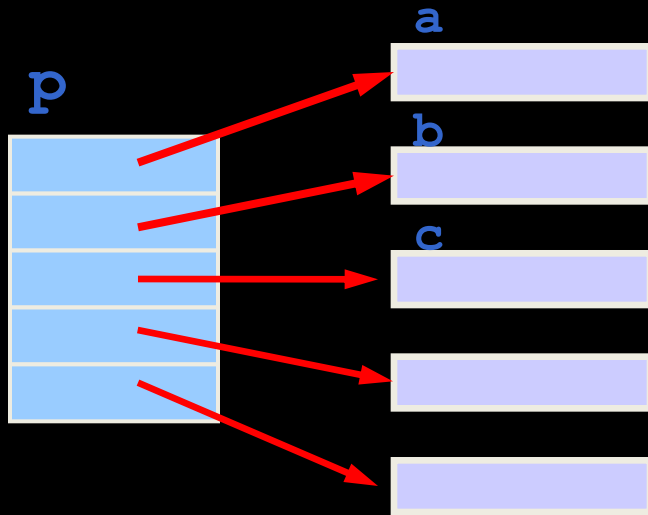

Dereferencing Array Pointers

*** (a+n) is identical to a[n]**

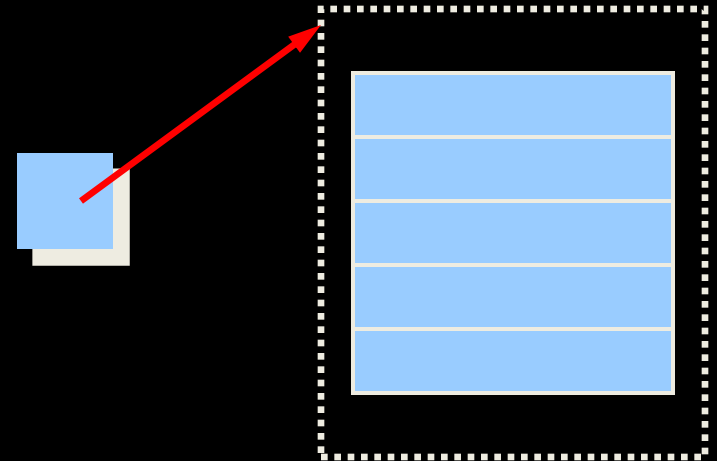

- Note: flexible pointer syntax

Array of Pointers & Pointers to Array

An array of Pointers

```
int a = 1, b = 2, c = 3;  
int *p[5];  
p[0] = &a;  
p[1] = &b;  
p[2] = &c;
```

A pointer to an array

```
int list[5] = {9, 8, 7, 6, 5};  
int *p;  
P = list; //points to 1st entry  
P = &list[0]; //points to 1st entry  
P = &list[1]; //points to 2nd entry  
P = list + 1; //points to 2nd entry
```

NULL pointer

- NULL is a special value that indicates an empty pointer
- If you try to access a NULL pointer, you will get an error

```
int *p;  
p = 0;  
cout << p << endl; //prints 0  
cout << &p << endl; //prints address of p  
cout << *p << endl; //Error!
```

Storing 2D Array in 1D Array

```
int twod[3][4] = {{0,1,2,3}, {4,5,6,7},  
                 {8,9,10,11}};
```

```
int oned[12];  
for(int i=0; i<3; i++){  
    for(int j=0; j<4 ; j++)  
        oned[i*4+j] = twod[i][j];  
}
```

Pointer to 2-Dimensional Arrays

table[i] =
&table[i][0]
refers to
the *address*
of the *ith*
row

```
int table[3][4] = {{1,2,3,4},  
{5,6,7,8},{9,10,11,12}};
```

*(table[i]+j)
= table[i][j]

```
for(int i=0; i<3; i++){  
    for(int j=0; j<4; j++)  
        cout << *(* (table+i)+j);  
    cout << endl;  
}
```

What is
**table
?

Dynamic Objects

Memory Management

- Static Memory Allocation
 - Memory is allocated at compilation time
- Dynamic Memory
 - Memory is allocated at running time

Static vs. Dynamic Objects

- Static object

(variables as declared in function calls)

- Memory is acquired automatically
- Memory is returned automatically when object goes out of scope

- Dynamic object

- Memory is acquired by program with an allocation request
 - `new operation`
- Dynamic objects can exist beyond the function in which they were allocated
- Object memory is returned by a deallocation request
 - `delete operation`

Memory Allocation

```
{
  int a[200];
  ...
}
```

```
int* ptr;
ptr = new int[200];
...
delete [] ptr;
```

Object (variable) creation: New

Syntax

```
ptr = new SomeType;
```

where `ptr` is a pointer of type `SomeType`

Example

```
int* p = new int;
```

Object (variable) destruction:

Delete

Syntax

```
delete p;
```

storage pointed to by p is returned to free store and p is now undefined

Example

```
int* p = new int;  
*p = 10;  
delete p;
```

Array of New: dynamic arrays

- Syntax

```
P = new  
SomeType [Expression];
```

- Where

- P is a pointer of type `SomeType`
 - `Expression` is the number of objects to be constructed -- we are making an array
- Because of the flexible pointer syntax, P can be considered to be an array

Example

Dynamic Memory Allocation

- Request for “unnamed” memory from the Operating System

- ```
int *p, n=10;
p = new int;
```

- ```
p = new int[100];
```

- ```
p = new int[n];
```

# Memory Allocation Example

## Want an array of unknown size

```
#include <iostream>
using namespace std;
void main()
{
 int n;
 cout << "How many students? ";
 cin >> n;
 int *grades = new int[n];
 for(int i=0; i < n; i++){
 int mark;
 cout << "Input Grade for Student" << (i+1) << " ? :";
 cin >> mark;
 grades[i] = mark;
 }
 . . .
 printMean(grades, n); // call a function with dynamic array
 . . .
}
```

# Freeing (or deleting) Memory

# A Simple Dynamic List Example

```
cout << "Enter list size: ";
int n;
cin >> n;
int *A = new int[n];
if(n<=0){
 cout << "bad size" << endl;
 return 0;
}
initialize(A, n, 0); // initialize the array A with value 0
print(A, n);
A = addElement(A,n,5); //add an element of value 5 at the end of A
print(A, n);
A = deleteFirst(A,n); // delete the first element from A
print(A, n);
selectionSort(A, n); // sort the array (not shown)
print(A, n);
delete [] A;
```

# Initialize

```
void initialize(int list[], int size, int value) {
 for(int i=0; i<size; i++)
 list[i] = value;

}
```

# print()

```
void print(int list[], int size) {
 cout << "[";
 for(int i=0; i<size; i++)
 cout << list[i] << " ";
 cout << "]" << endl;
}
```

- **Remember in C++, array parameters are always passed by reference.** That is, `void print(int list[], int size) {...}` is the same as `void print(int * list , int size) {...}`

Note: no & used here, so, the pointer itself is passed by value

# Adding Elements

```
// for adding a new element to end of array
int* addElement(int list[], int& size, int value){
 int* newList = new int [size+1]; // make new array
 if(newList==0){
 cout << "Memory allocation error for addElement!" << endl;
 exit(-1);
 }
 for(int i=0; i<size; i++)
 newList[i] = list[i];
 if(size) delete [] list;
 newList[size] = value;
 size++;
 return newList;
}
```

# Delete the first element

```
// for deleting the first element of the array
int* deleteFirst(int list[], int& size){
 if(size <= 1){
 if(size) delete list;
 size = 0;
 return NULL;
 }
 int* newList = new int [size-1]; // make new array
 if(newList==0){
 cout << "Memory allocation error for deleteFirst!" << endl;
 exit(-1);
 }
 for(int i=0; i<size-1; i++) // copy and delete old array
 newList[i] = list[i+1];
 delete [] list;
 size--;
 return newList;
}
```

# Adding Element (version 2)

```
// for adding a new element to end of array
// here "list" is a reference to a pointer variable: if the value of
// the pointer is changed in function, the change is global.
void addElement(int * & list, int & size, const int value){

 int * newList = new int [size + 1];

 if(newList == NULL){
 cout << "Memory allocation error for addElement!" << endl;
 exit(-1);
 }

 for(int i = 0; i < size; i++)
 newList[i] = list[i];

 if(size) delete [] list;

 newList[size] = value;
 size++;
 list = newList;
 return;
}
```

# Deleting Element (version 2)

```
void deleteFirst(int * & list, int & size){

 if(size <= 1){
 if(size)
 delete list;
 list = NULL;
 size = 0;
 return;
 }

 delete list; // delete the first element
 list++;
 size--;
 return;
}
```

# Another Main program

```
int main(){

 int * A = NULL;
 int size = 0;
 int i;

 for(i = 0; i < 10; i++)
 addElement(A, size, i);

 for(i = 0; i < 10; i++)
 cout << A[i] << " ";
 cout << endl;

 for(i = 0; i < 4; i++)
 deleteFirst(A, size);

 for(i = 0; i < 6; i++)
 cout << A[i] << " ";
 cout << endl;

 return 0;
}
```

|                            |
|----------------------------|
| <b>0 1 2 3 4 5 6 7 8 9</b> |
| <b>4 5 6 7 8 9</b>         |

# Dangling Pointer Problem

```
int *A = new int[5];
for(int i=0; i<5; i++)
 A[i] = i;
int *B = A;
```

```
delete [] A;
B[0] = 1; // illegal!
```

# Memory Leak Problem

```
int *A = new int [5];
for(int i=0; i<5; i++)
 A[i] = i;
```

These locations cannot be accessed by program

```
A = new int [5];
```

# A Dynamic 2D Array

✉ A dynamic array is an array of pointers to save space when not all rows of the array are full.

✉ `int **table;`

```
table = new int*[6];
...
table[0] = new int[4];
table[1] = new int[7];
table[2] = new int[1];
table[3] = new int[3];
table[4] = new int[2];
table[5] = NULL;
```

# Memory Allocation

```
int **table;
```

```
table = new int*[6];
```

```
table[0]= new int[3];
```

```
table[1]= new int[1];
```

```
table[2]= new int[5];
```

```
table[3]= new int[10];
```

```
table[4]= new int[2];
```

```
table[5]= new int[6];
```

```
table[0][0] = 1; table[0][1] = 2; table[0][2] = 3;
```

```
table[1][0] = 4;
```

```
table[2][0] = 5; table[2][1] = 6; table[2][2] = 7; table[2][3]
= 8; table[2][4] = 9;
```

```
table[4][0] = 10; table[4][1] = 11;
```

```
cout << table[2][5] << endl;
```

# Memory Deallocation

- Memory leak is a serious bug!
- Each row must be deleted individually
- Be careful to delete each row before deleting the table pointer.

```
- for (int i=0; i<6; i++)
 delete [] table[i];
delete [] table;
```

## Create a matrix of any dimensions, m by n:

```
int m, n;
cin >> m >> n >> endl;

int** mat;

mat = new int*[m];

for (int i=0; i<m; i++)
 mat[i] = new int[n];
```

## Put it into a function:

```
int m, n;
cin >> m >> n >> endl;
int** mat;
mat = imatrix(m, n);
...

int** imatrix(nr, nc) {
 int** m;
 m = new int*[nr];
 for (int i=0; i<nr; i++)
 m[i] = new int[nc];
 return m;
}
```
